A new software-defined radio receiver for the BRAMS network Replacement of the analogue ICOM receiver by a software-defined radio

Michel Anciaux

Royal Belgian Institute for Space Aeronomy

9th March 2019

Issues with current ICOM receiver Alternatives for a new receiver Funcube Dongle Pro plus Other receivers

Current receiving stations

Introduction

Many stations in the BRAMS network have experienced problems with their analogue receiver. Until now, all failed units could be either repaired or replaced but this is not sustainable. A new type of receiver must now be chosen.

Issues with current ICOM receiver Alternatives for a new receiver Funcube Dongle Pro plus Other receivers

Current receiving stations

Introduction

Many stations in the BRAMS network have experienced problems with their analogue receiver. Until now, all failed units could be either repaired or replaced but this is not sustainable. A new type of receiver must now be chosen.

A first candidate based on a software-defined radio has been evaluated and its suitability will be presented here.

Reliability Availability Performance limitations

Reliability issue with ICOM receiver

Why has reliability become a concern?

• ageing: most receivers have been operating continuously for several years

Reliability Availability Performance limitations

Reliability issue with ICOM receiver

Why has reliability become a concern?

- ageing: most receivers have been operating continuously for several years
- many have already failed (18), some could be repaired (13 so far)

Reliability Availability Performance limitations

Reliability issue with ICOM receiver

Why has reliability become a concern?

- ageing: most receivers have been operating continuously for several years
- many have already failed (18), some could be repaired (13 so far)
- most failures have been of the same type (sharp drop in sensitivity) but new types of degradation have already been observed (on at least 2 units)

Reliability Availability Performance limitations

Reliability issue with ICOM receiver

Why has reliability become a concern?

- ageing: most receivers have been operating continuously for several years
- many have already failed (18), some could be repaired (13 so far)
- most failures have been of the same type (sharp drop in sensitivity) but new types of degradation have already been observed (on at least 2 units)
- This can only get worse !

Reliability Availability Performance limitations

Availability issue

Why is replacing the receiver becoming impossible?

- ● ● ●

Reliability Availability Performance limitations

Availability issue

Why is replacing the receiver becoming impossible?

• This model is no longer produced

Reliability Availability Performance limitations

Why is replacing the receiver becoming impossible?

- This model is no longer produced
- Alternative analogue models are considerably more expensive

Reliability Availability Performance limitations

Why is replacing the receiver becoming impossible?

- This model is no longer produced
- Alternative analogue models are considerably more expensive
- The market trend is that analogue receivers are being replaced by software defined radios

Reliability Availability Performance limitations

Performance limitations

There are also some limitation with the current receivers:

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Frequency stability

The Funcube exhibits frequency drifts (as does the ICOM receiver).

Michel Anciaux A new receiver for BRAMS

A 1

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Frequency stability

The Funcube exhibits frequency drifts (as does the ICOM receiver).

• The local oscillator frequency has a significant temperature dependence (4.6 Hz / °C).

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Frequency stability

The Funcube exhibits frequency drifts (as does the ICOM receiver).

- The local oscillator frequency has a significant temperature dependence (4.6 Hz / °C).
- It cannot be locked to an external reference.

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Frequency stability

The Funcube exhibits frequency drifts (as does the ICOM receiver).

- The local oscillator frequency has a significant temperature dependence (4.6 Hz / °C).
- It cannot be locked to an external reference.

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Frequency stability

The Funcube exhibits frequency drifts (as does the ICOM receiver).

- The local oscillator frequency has a significant temperature dependence (4.6 Hz / °C).
- It cannot be locked to an external reference.

To mitigate this effect, the Funcube should have its temperature stabilised (not a major hurdle thanks to its very low mass).

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Time stamping

As with the current set up, the data must be timestamped with sub-millisecond accuracy.

< 47 ▶

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Time stamping

As with the current set up, the data must be timestamped with sub-millisecond accuracy.

• The current method of simultaneously sampling the receiver signal and the GPS signal(NMEA frame + 1-PPS) is not usable.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Time stamping

As with the current set up, the data must be timestamped with sub-millisecond accuracy.

- The current method of simultaneously sampling the receiver signal and the GPS signal(NMEA frame + 1-PPS) is not usable.
 - the data from the funcube is digital and does not go through an audio channel

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Time stamping

As with the current set up, the data must be timestamped with sub-millisecond accuracy.

- The current method of simultaneously sampling the receiver signal and the GPS signal(NMEA frame + 1-PPS) is not usable.
 - the data from the funcube is digital and does not go through an audio channel
 - simultaneous sampling of GPS and radio signals cannot be guaranteed

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Time stamping

As with the current set up, the data must be timestamped with sub-millisecond accuracy.

- The current method of simultaneously sampling the receiver signal and the GPS signal(NMEA frame + 1-PPS) is not usable.
 - the data from the funcube is digital and does not go through an audio channel
 - simultaneous sampling of GPS and radio signals cannot be guaranteed
- A new method is needed.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

New time stamping method

Usable timestamps can be produced by doing the following:

A 1

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

New time stamping method

Usable timestamps can be produced by doing the following:

• Save a time stamp for every 1000 samples read from the Funcube.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

New time stamping method

Usable timestamps can be produced by doing the following:

- Save a time stamp for every 1000 samples read from the Funcube.
- Keep the linux-system clock synchronised with the GPS 1-PPS.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

New time stamping method

Usable timestamps can be produced by doing the following:

- Save a time stamp for every 1000 samples read from the Funcube.
- Keep the linux-system clock synchronised with the GPS 1-PPS.
- Keep the scheduling jitter low by minimizing activity.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

New time stamping method

Usable timestamps can be produced by doing the following:

- Save a time stamp for every 1000 samples read from the Funcube.
- Keep the linux-system clock synchronised with the GPS 1-PPS.
- Keep the scheduling jitter low by minimizing activity.
- Rely on the stability of the sampling rate inside the Funcube.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Use of time stamps

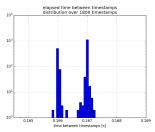

The timestamps are affected by the scheduling jitter.

< 4 →

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Use of time stamps

2 modes

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Use of time stamps

The timestamps are affected by the scheduling jitter.

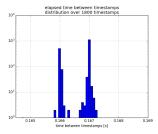

- mean time difference: 166.7 ms as expected
- 2 modes
- occasional excursions of a few ms

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Use of time stamps

The timestamps are affected by the scheduling jitter.

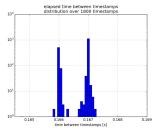

- mean time difference: 166.7 ms as expected
- 2 modes
- occasional excursions of a few ms

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Use of time stamps

The timestamps are affected by the scheduling jitter.

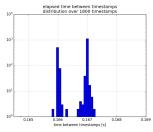

- mean time difference: 166.7 ms as expected
- 2 modes
- occasional excursions of a few ms

• A correction can be applied by performing a linear regression on the timestamps.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Use of time stamps

The timestamps are affected by the scheduling jitter.

- mean time difference: 166.7 ms as expected
- 2 modes
- occasional excursions of a few ms

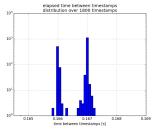

< 47 ►

- A correction can be applied by performing a linear regression on the timestamps.
- This should work because the sampling rate is constant, the system clock has a very low jitter (<1µs) and there is a time stamp every 1000 samples.

Test configuration Receiver sensitivity Frequency stability Time stamping Conclusions

Use of time stamps

The timestamps are affected by the scheduling jitter.

- mean time difference: 166.7 ms as expected
- 2 modes
- occasional excursions of a few ms
- A correction can be applied by performing a linear regression on the timestamps.
- This should work because the sampling rate is constant, the system clock has a very low jitter ($<1\mu$ s) and there is a time stamp every 1000 samples.
- This must, of course, be tested.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Testing of time stamping method

In order to validate the time stamping method, a test was devised:

A 1

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Testing of time stamping method

In order to validate the time stamping method, a test was devised:

• The input RF signal (49.97 MHz) was modulated by the 1-PPS from the GPS receiver.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Testing of time stamping method

- The input RF signal (49.97 MHz) was modulated by the 1-PPS from the GPS receiver.
- The demodulated envelope was recovered from the upper side band.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Testing of time stamping method

- The input RF signal (49.97 MHz) was modulated by the 1-PPS from the GPS receiver.
- The demodulated envelope was recovered from the upper side band.
- Successive rising edges should occur at 1-second intervals.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

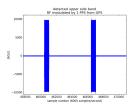

Testing of time stamping method

- The input RF signal (49.97 MHz) was modulated by the 1-PPS from the GPS receiver.
- The demodulated envelope was recovered from the upper side band.
- Successive rising edges should occur at 1-second intervals.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

- Successive rising edges should occur at 1-second intervals.

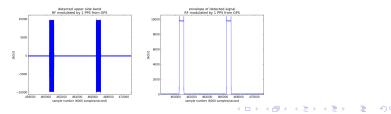

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Testing of time stamping method

In order to validate the time stamping method, a test was devised:

- The input RF signal (49.97 MHz) was modulated by the 1-PPS from the GPS receiver.
- The demodulated envelope was recovered from the upper side band.
- Successive rising edges should occur at 1-second intervals.

Michel Anciaux

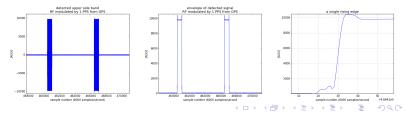

A new receiver for BRAMS

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Testing of time stamping method

In order to validate the time stamping method, a test was devised:

- The input RF signal (49.97 MHz) was modulated by the 1-PPS from the GPS receiver.
- The demodulated envelope was recovered from the upper side band.
- Successive rising edges should occur at 1-second intervals.

Michel Anciau×

A new receiver for BRAMS

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

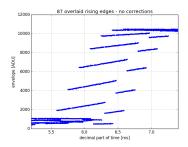

Results of time stamping test

Ideally all rising edges should occur at the same decimal part of a second. The initial jitter should be reduced by the time correction.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Results of time stamping test

Ideally all rising edges should occur at the same decimal part of a second. The initial jitter should be reduced by the time correction.

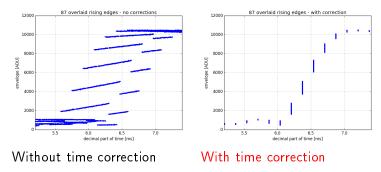

Without time correction

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Results of time stamping test

Ideally all rising edges should occur at the same decimal part of a second. The initial jitter should be reduced by the time correction.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

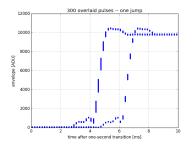

Anomaly

Once the time correction has been applied, all the rising edges should occur at the same time after the one-second transition. Unfortunately, that is not always the case.

Dropped samples

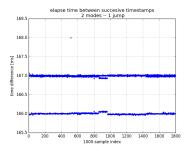

Evidence of the dropped samples can be found by observing the elapsed time between consecutive time stamps.

- nominal time difference: 167 ms
- 2 modes due to scheduling jitter

< 47 ▶

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Dropped samples

Evidence of the dropped samples can be found by observing the elapsed time between consecutive time stamps.

- nominal time difference: 167 ms
- 2 modes due to scheduling jitter
- 1 jump at index ≈510: dropped samples ==> increased time between timestamps

< 口 > < 同 >

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Identifying the jumps

Fortunately, the jumps come in multiples of 2 ms and can readily be identified.

• observe the time between time stamps

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Identifying the jumps

Fortunately, the jumps come in multiples of 2 ms and can readily be identified.

- observe the time between time stamps
- apply some smoothing function

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Identifying the jumps

Fortunately, the jumps come in multiples of 2 ms and can readily be identified.

- observe the time between time stamps
- apply some smoothing function
- find discontinuities greater than 1 ms and mark the corresponding time stamps as dubious

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

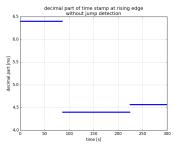

Results of time stamping test with jump identification

The effect of the jump detection can be seen by looking at the time of the rising edge as a function of time.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Results of time stamping test with jump identification

The effect of the jump detection can be seen by looking at the time of the rising edge as a function of time.

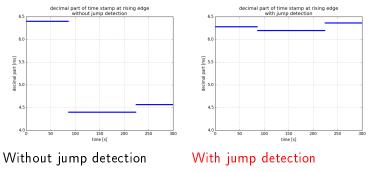

Without jump detection

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Results of time stamping test with jump identification

The effect of the jump detection can be seen by looking at the time of the rising edge as a function of time.

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Long term test to validate the time stamping method

The previous time stamping test was run continuously for more than 16 hours yielding the following results:

• 58759 rising edges out of 59082 pulses were used (99.45%)

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Long term test to validate the time stamping method

- 58759 rising edges out of 59082 pulses were used (99.45%)
- time between rising edges:

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Long term test to validate the time stamping method

- 58759 rising edges out of 59082 pulses were used (99.45%)
- time between rising edges:
 - mean: 1000.0004 ms

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Long term test to validate the time stamping method

- 58759 rising edges out of 59082 pulses were used (99.45%)
- time between rising edges:
 - mean: 1000.0004 ms
 - standard deviation: 0.0146 ms

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Long term test to validate the time stamping method

- 58759 rising edges out of 59082 pulses were used (99.45%)
- time between rising edges:
 - mean: 1000.0004 ms
 - standard deviation: 0.0146 ms
 - max deviation: 0.166 ms

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Long term test to validate the time stamping method

- 58759 rising edges out of 59082 pulses were used (99.45%)
- time between rising edges:
 - mean: 1000.0004 ms
 - standard deviation: 0.0146 ms
 - max deviation: 0.166 ms
 - min deviation: -0.167 ms

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Long term test to validate the time stamping method

- 58759 rising edges out of 59082 pulses were used (99.45%)
- time between rising edges:
 - mean: 1000.0004 ms
 - standard deviation: 0.0146 ms
 - max deviation: 0.166 ms
 - min deviation: -0.167 ms
- the time stamps were thus within one sampling period of the actual rising edge

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

Long term test to validate the time stamping method

- 58759 rising edges out of 59082 pulses were used (99.45%)
- time between rising edges:
 - mean: 1000.0004 ms
 - standard deviation: 0.0146 ms
 - max deviation: 0.166 ms
 - min deviation: -0.167 ms
- the time stamps were thus within one sampling period of the actual rising edge
- for the 323 seconds where the time stamp was declared dubious, the time error was bounded by the measured discontinuity of a few ms

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

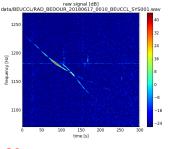

Simultaneous observation with BEUCCL

During nearly 5 days, the Funcube and the station at Uccle (BEUCCL with an ICOM receiver) observed the same signal to allow for operational comparisons (that have yet to be carried out).

Test configuration Receiver sensitivity Frequency stability **Time stamping** Conclusions

New receivers will also soon be needed for the interferometer and the RADAR.

• It may be convenient to use the same model of receiver there as well.

Airspy R2 SDRplay RSP2 Preliminary tests of SDRplay RSP2 Interferometer and RADAR

New receivers for the interferometer and the for RADAR

New receivers will also soon be needed for the interferometer and the RADAR.

- It may be convenient to use the same model of receiver there as well.
- For these two applications, however, the LO must be phase-locked to a common reference. This rules out the Funcube of course.

New receivers for the interferometer and the for RADAR

New receivers will also soon be needed for the interferometer and the RADAR.

- It may be convenient to use the same model of receiver there as well.
- For these two applications, however, the LO must be phase-locked to a common reference. This rules out the Funcube of course.
- The SDRplay RSP2 would probably be suitable (to be confirmed by phase stability tests on a pair of receivers).
