

Overview of major shower observations 2016-2017 by the BRAMS network

Cis Verbeeck, Hervé Lamy, Stijn Calders, Cédric Tétard, Antonio Martínez Picar

IMC 2017, Petnica, September 21-24, 2017

BRAMS network

- One transmitter at Dourbes (left)
- Frequency: 49.970 MHz
- Power: 150 W
- 26 receiver stations in Belgium

Spectrograms

Horizontal axis: time (duration = 5 minutes)

Why you didn't see BRAMS meteor activity plots yet...

- One spectrogram every 5 minutes
- > 288 spectrograms per day
- Over a "spectrokilogram" for a few days of shower observations
- Too much to manually detect meteors in all spectrograms ourselves
- Automatic detection of meteors not yet up to the task

Perseids 2016, Humain: sporadic background

Perseids 2016, Humain: sporadic background

Number of meteor reflections

Perseids 2016, Ottignies: sporadic background

Number of meteor reflections

Perseids 2016, Humain

Number of meteor reflections

Perseids 2016, Humain

Number of meteor reflections > 10 s

Geminids 2016, Neufchâteau

Number of meteor reflections

Geminids 2016, Neufchâteau

Number of meteor reflections > 10 s

Quadrantids 2017, Kampenhout

Number of meteor reflections

Quadrantids 2017, Kampenhout

Number of meteor reflections > 10 s

Perseids 2017, Humain

Number of meteor reflections

Perseids 2017, Humain

Number of meteor reflections > 10 s

Conclusions

- The BRAMS team has established a consistent method to estimate the sporadic background and subtract it from the total activity to obtain shower activity.
- Most showers are overwhelmed by the many faint sporadic meteors. Showers stand out better when considering only long duration reflections.
- The resulting shower rates have to be corrected for the sensitivity of the setup (Observability Function), which is highly dependent on radiant-setup geometry and antenna gains.

Near future

- Observability Function code expected to be ready end 2017
- What may it bring?
